QVAC Discord	AI questions. Tag Victor	discord.gg/h8aESjdCp

Where to start

- New to this: start with the WDK quickstart, or the browser lab Victor mentioned in the session.
- Building for mobile: start from the mobile wallet starter and its setup guide.
- Want a wallet assistant: follow the QVAC JavaScript quickstart and use Wally as a reference.
- Testnet is fine for your demo. The workshop example used Sepolia, an Ethereum test network.

The payment flow to build around

- Check the address, the network and the token.
- Check the balance and get a fee quote.
- Show the recipient, amount, fee and network, and let the person approve or cancel.
- After approval, the wallet signs and submits the transaction.
- Check the receipt. Show the payment as pending until the network confirms it.

Five project ideas from Victor

- **Send money to family:** pick a saved recipient, review the address and fee, send USDT.
- **QR checkout for a market vendor:** the customer scans to pay, the vendor sees pending and then confirmed.
- **Savings group:** members contribute USDT, see who has paid in and whose turn it is to receive the payout.
- **Wallet assistant:** the person types a request, QVAC interprets it, the app checks the details and WDK sends once the person approves.
- **Poor-connection resilience:** show the last known payment status and re-check the same transaction on reconnect, so nobody pays twice.

Tips for your demo

- Start with the person and what they are trying to do, then walk through one payment from review to receipt.
- Sender and recipient need wallets on the same network that support the same token.
- Share the wallet address. Keep the recovery phrase private.
- Show what happens when one thing goes wrong and how the person gets unstuck.
- If part of your demo is simulated, label it on screen.
- You may build on existing code, but you must show new work done during the hackathon.
